FOREIGN DIRECT INVESTMENT - GROWTH NEXUS: A REVIEW OF THE RECENT LITERATURE
OZTURK, Ilhan*

Abstract
This paper reviews the literature dealing with the effects of FDI on Growth. Numerous empirical studies have been conducted to investigate whether growth is influenced by FDI. The overall evidence is best characterized as mixed as the results are regarding to the importance of labor costs, openness, investment climate, countries considered (developed vs developing) and fiscal incentives. However, free trade zones, trade regime, the human capital base in the host country, financial market regulations, banking system, infrastructure quality, tax incentives, market size, regional integration arrangements and economic/political stability are very important determinant for FDI that creates a positive impact on overall economic growth. In summary, consensus has been reached among academia and practitioners that FDI tends to have significant effect on economic growth through multiple channels such as capital formation, technology transfer and spillover, human capital (knowledge and skill) enhancement, and so on.

Key words: FDI, Economic Growth
JEL Classification: F39, O40

I. Introduction
During the fluctuations of capital flows in the 1990s, foreign direct investment (FDI) was the main source of flows to developing countries. Contrary to other capital flows, FDI is less volatile and does not show a pro-cyclical behaviour. It has therefore become the “favourite capital inflows” for developing countries. The FDI increased rapidly during the late 1980s and the 1990s in almost every region of the world revitalizing the long and contentious debate about the costs and benefits of FDI inflows. On one hand many would argue that, given appropriate policies and a basic level of development, FDI can play a key role in the process of creating a

* Faculty of Economics and Administrative Sciences, Cag University, 33800, Mersin, Turkey. Email: ilhanozturk@cag.edu.tr
better economic environment. On the other hand potential drawbacks do exist, including a deterioration of the balance of payments as profits are repatriated and negative impacts on competition in national markets. At present, the consensus view seems to be that there is a positive association between FDI inflows and growth provided receiving countries have reached a minimum level of educational, technological and/or infrastructure development.

As mentioned by Busse and Groizard (2005), the enormous increase in FDI flows across countries is one of the clearest signs of the globalisation of the world economy over the past 20 years. Total FDI flows increased from some US $55 billion in 1985 to US $1,511 billion before falling back to US $573 billion in 2003 (World Bank 2005). Even as a share of Gross Domestic Product (GDP), we do observe an enormous increase in the significance of FDI. In high-income countries, this share increased from some 0.5 to 1.0 per cent in the 1980s to more than 5 per cent in 2000 and then declined to 1.4 per cent in 2003 (Figure 1). While the increase in FDI inflows was less drastic in low- and middle-income countries, the percentage of FDI in GDP remained at more than 2 per cent after the year 2000, indicating a slightly higher significance of FDI flows in developing countries in the most recent period.

In summary, consensus has been reached among academia and practitioners that FDI tends to have significant effect on economic growth through multiple channels such as capital formation, technology transfer and spillover, human capital (knowledge and skill) enhancement, and so on. The rest of the paper is organized as follows: Section II describes the theory. Section III reports the literature survey, and the last section is the conclusion.

2. Theory
The relationship between FDI and economic growth has motivated a voluminous empirical literature focusing on both developed and developing countries. Several studies find a clear positive link, while others do not. Research that focuses on data from only less developed countries (LDC’s) has tended to find a clear positive relationship, while studies that have ignored this distinction, or have focused on data from only developed countries (DC’s), have found no growth benefit for the recipient country. Neoclassical models of growth as well as endogenous growth models provide the basis for most of the empirical work on the FDI-growth relationship. The relationship has been studied by explaining four main channels: (i) determinants of growth, (ii) determinants of FDI, (iii) role of multinational firms in host countries, and (iv) direction of causality between the two variables (Chowdhury and Mavrotas, 2005).

According to the neoclassical growth theory, economic growth generally comes from two sources: factor accumulation and total factor productivity (TFP) growth (Felipe, 1997). Of these two sources, the empirical literature usually focuses more on studying the growth of factor inputs than the growth in TFP. This is due to the fact that factor growth is easier to quantify and analyze while difficulties abound in the measurement of TFP growth due to the lack of appropriate econometric modeling techniques as well as unavailability of appropriate data.

As opposed to the limited contribution that the neoclassical growth theory accredits to FDI, the endogenous growth literature points out that, FDI can not only contribute to economic growth through capital formation and technology transfers (Blomstrom et al., 1996; Borensztein et al., 1995) but also do so through the
augmentation of the level of knowledge through labor training and skill acquisition (de Mello 1997, 1999).

In the framework of endogenous growth models, several channels are at work. More precisely, three main channels can be detected through which FDI affects growth. First, FDI increases capital accumulation in the receiving country by introducing new inputs and technologies (Dunning, 1993; Blomstrom et al., 1996; Borensztein et al. 1998). Second, it raises the level of knowledge and skills in the host country through labor and manager training (de Mello, 1996, 1999). Third, FDI increases competition in the host country industry by overcoming entry barriers and reducing the market power of existing firms.

As mentioned by Chowdhury and Mavrotas (2005), a large number of empirical studies on the role of FDI in host countries suggest that FDI is an important source of capital, complements domestic private investment, is usually associated with new job opportunities and enhancement of technology transfer and spillover, human capital (knowledge and skill) enhancement, and boosts overall economic growth in host countries. On the other hand, a number of firm-level studies do not lend support for the view that FDI promotes economic growth.

Concerning developing countries, macro-empirical work on the FDI-growth relationship has shown that—subject to a number of crucial factors, such as the trade regime, the human capital base in the host country, financial market regulations, banking system and

---

the degree of openness in the economy—FDI has a positive impact on overall economic growth\(^3\).

More recently, a series of papers have been published that examined the linkages between the effectiveness and regulations of financial markets, FDI and growth. In essence, Hermes and Lensink (2003), Durham (2004) and Alfaro et al. (2004) all find that countries with better financial systems and financial market regulations can exploit FDI more efficiently and achieve a higher growth rate. These studies argue that countries need not only a sound banking system, but also a functioning financial market to allow entrepreneurs to obtain credit to start a new business or expand an existing one. The emerging literature on FDI stipulates that FDI’s positive impact on growth depends on local conditions and absorptive capacities. Essential among these capacities is financial development. These results imply that countries should reform their domestic financial system before working on attracting FDI. Vast literature on the determinants of FDI in developing countries clearly indicates the importance of infrastructure, skills, macroeconomic stability and sound institutions for attracting FDI flows\(^4\).

During the last decade, a number of interesting studies of the role of foreign direct investment in stimulating economic growth has appeared. In the survey of de Mello (1997), two main channels through which FDI may be growth enhancing are listed. First, FDI can encourage the adoption of new technology in the production process through capital spillovers. Second, FDI may stimulate knowledge transfers, both in terms of labour training and skill acquisition and by introducing alternative management practices and better organizational arrangements. A survey by OECD (2002) underpins these observations and documents that 11 out of 14 studies

have found FDI to contribute positively to income growth and factor productivity. According to de Mello (1997) and OECD (2002), FDI affects growth is likely to depend on the economic and technological conditions in the host country. In particular, it seems that developing countries have to reach a certain level of development, in education and/or infrastructure, before they are able to capture potential benefits associated with FDI. Therefore, FDI seems to have more limited growth impact in technologically less advanced countries. The main result of OECD survey (2002) is that there seems to be a strong relationship between FDI and growth. Although this relationship is highly heterogeneous across countries generally agree that FDI, on average, has an impact on growth in the Granger-causal sense.

While the literature has heeded the importance of FDI to growth and development, it also realizes that economic growth could be an important factor in attracting FDI flows. The importance of economic growth to attracting FDI is closely linked to the fact that FDI tends to be an important component of investing firms’ strategic decisions.

As indicated in several empirical studies\(^5\), according to the market size hypothesis, the markets with large population size and/or rapid economic growths (as measured by real GDP per capita or its growth) tend to give multinational firms more opportunities to generate greater sales and profits and thus become more attractive to their investments. Wheeler and Mody (1992) have tried to determine the relative importance of these two explanatory variables and found that market size is more important for developed countries, while per capita GDP for developing countries.

Next to the direct increase of capital formation of the recipient economy, FDI may also help increasing growth by introducing new technologies, such as new production processes and techniques, managerial skills, ideas, and new varieties of capital goods. In the new growth literature the importance of technological change for economic growth has been emphasised (Grossman and

The growth rate of less developed countries (LDCs) is perceived to be highly dependent on the extent to which these countries can adopt and implement new technologies available in developed countries (DCs). By adapting new technologies and ideas (i.e. technological diffusion) they may catch up to the levels of technology in DCs. One important channel through which adoption and implementation of new technologies and ideas by LDCs may take place is FDI. The new technologies they introduce in these countries may spillover from subsidiaries of multinationals to domestic firms (Findlay, 1978). The use of new technologies may be important in contributing to higher productivity of capital and labour in the host country. The spillover may take place through demonstration and/or imitation (domestic firms imitate new technologies of foreign firms), competition (entrance of foreign firms leads to pressure on domestic firms to adjust their activities and to introduce new technologies), linkages (spillovers through transactions between multinationals and domestic firms), and/or training (domestic firms upgrade the skills of their employees to enable them to work with the new technologies) (Kinoshita, 1998; Sjöholm, 1999a).

The next question is what conditions in the host country are important to maximise the technology spillovers discussed above? In the literature it has been emphasised by some that the spillover effect can only be successful given certain characteristics of the environment in the host country. These characteristics together determine the absorption capacity of technology spillovers of the host country. Thus, FDI can only contribute to economic growth through spillovers when there is a sufficient absorptive capacity in the host country. Several country studies have been carried out, providing diverging results on the role of FDI spillovers with respect to stimulating economic growth. These studies deal with the productivity effects of FDI spillovers on firms or plants using micro level data. Whereas positive effects from spillovers have been found for, e.g. Mexico (Blomström and Persson, 1983; Blomström and Wolff, 1994; Kokko, 1994), Uruguay (Kokko et al., 1996) and Indonesia (Sjöholm, 1999b), no spillovers were traced in studies for Morocco (Haddad and Harrison, 1993) and Venezuela (Aitken and
Harrison, 1999). These diverging results may underline the crucial role of certain host country characteristics necessary to let FDI contribute positively to economic growth through spillovers. They emphasise the difference in absorptive capacity between countries to adopt FDI.

Some authors argue that the adoption of new technologies and management skills requires inputs from the labour force. High-level capital goods need to be combined with labour that is able to understand and work with the new technology. Therefore, technological spillover is possible only when there is a certain minimum, or ‘threshold’ level of human capital available in the host country (Borensztein, et al., 1998). This suggests that FDI and human capital are complementary in the process of technological diffusion. Other authors argue that the process of technological spillovers may be more efficient in the presence of well-functioning markets. Under these circumstances, the environment in which FDI operates ensures competition and reduces market distortions, enhancing the exchange of knowledge among firms (Bhagwati, 1978; Ozawa, 1992; Balasubramanyam, et al., 1996).

Some authors stress that the establishment of property rights – in particular intellectual property rights – is crucial to attract high technology FDI (Smarzynska, 1999). If intellectual property rights are only weakly protected in a country, foreign firms will undertake low technology investments, which reduces the opportunities for spillover effects and improvements of productivity of domestic firms.

3. Literature survey of empirical studies

Many empirical contributions have tried to explain the relationship between FDI and growth (see Table 1). A detailed literature survey on the effects of FDI on growth has been outlined in this section. As it can be seen in the most of these studies, FDI has positive effect on growth.

| Busse and Groizard (2005) | 82 countries | 1975-2003 | Effect depends on regulations and institutional framework

| Darrat et al. (2005) | 6 MENA and 17 CEE countries | 1979-2002 | The effect of FDI inflow on economic growth is generally negative or statistically insignificant in MENA and non-EU accession CEE countries. However, it is positive in the case of EU accession countries of the CEE region.

| Bacic et al. (2005) | 11 transition economies | 1994-2002 | Insignificant and mixed results

| Karbasi et al. (2005) | 42 countries | 1971-2000 | Positive effect. The contribution of FDI on economic growth is enhanced by its positive interaction with human capital and sound macroeconomic policies and institutional stability.

4. Conclusion
This paper provides an extensive survey of the literature on FDI and Growth, examining both the theory that underlies the work in this area and the results of empirical studies published since 1986. Overall, a larger number of studies appear to favour the conventional assumption that FDI has positive effect on growth. The consensus has been reached among academia and practitioners that FDI tends to have significant effect on economic growth through multiple channels such as capital formation, technology transfer and spillover, human capital (knowledge and skill) enhancement, and so on.
A number of policy implications emerge from the study. For instance, results suggest that the country’s capacity to progress on economic growth will depend on its policies to promote FDI. The most efficient way to attract FDI is to focus on straighten the deficiencies on the following areas; such as free trade zones, trade regime, tax incentives, the human capital base in the host country, financial market regulations, banking system (financial system), infrastructure quality, tax incentives, market size, regional integration arrangements and economic/political stability.
